FRANK-WOLFE BAYESIAN QUADRATURE:
PROBABILISTIC INTEGRATION WITH THEORETICAL GUARANTEES

AUTHORS

ACHRAF BZILI, NICOLAS CLOAREC

Notations

We start with some notations we will use along this report.

- $p(\cdot)$ denotes the function $p : x \mapsto p(x)$.

Introduction

The goal of this article [1] is to compute efficiently the integrals of the form $\int_{\mathcal{X}} f(x)p(x)dx$ where $\mathcal{X} \subseteq \mathbb{R}^d$ is a measurable space, $d \geq 1$ integer representing the dimension of the problem, p a probability density with respect to the Lebesgue measure on \mathcal{X} and $f : \mathcal{X} \rightarrow \mathbb{R}$ is a *test-function*.

We will use the common approximation

$$\int_{\mathcal{X}} f(x)p(x)dx \approx \sum_{i=1}^n w_i f(x_i) \quad (1)$$

but of course the real challenge lies in the choice of sequences $\{x_i\}$ and $\{w_i\}$:

- **Monte Carlo:** $w_i = \frac{1}{n}$ and x_i realization of multivariate random variable $X_i \stackrel{iid}{\sim} X$ where X has $p(\cdot)$ as probability distribution.
- **Kernel herding:**
- **Quasi-Monte Carlo:**

In the **Frank-Wolfe Bayesian Quadrature**, we have

- 🔗 $\{w_i\}$ which appear naturally in the Bayesian Quadrature by taking the expectation of a posterior distribution (described in section 2)
- 🔗 $\{x_i\}$ which are chosen to minimize the posterior variance of our estimator (described in section 3)

The main interest of the method developed in [1] is the super fast *exponential* convergence to the true value compared to the other methods mentioned above.

1 Theoretical framework

2 Bayesian Quadrature

3 Frank-Wolfe algorithm
